Where to use

1. News

Problem a user visits a news site, the site presents it with a news header, and a user either clicks on this header or not.

Goal to maximize the number of clicks

Assumption

each user is drawn independently from a fixed distribution over users

In each round, the click happens independently with a probability that depends only on the chosen header.

2. Ad selection

Problem for a user, if ad a is displayed, the website observes whether the user clicks on the ad, in which case the advertiser pays some amount $v_a \in [0,1]$

Goal to maximize the paid amount (ad = arm, reward = paid amount)

Assumption

The paid amount v_a depends only on the displayed ad, but does not change over time.

Introduction

Problem

Problem protocol: Multi-armed bandits

In each round $t \in [T]$:

- 1. Algorithm picks arm $a_t \in \mathcal{A}$.
- 2. Algorithm observes reward $r_t \in [0,1]$ for the chosen arm.
- 1. The restriction to the interval [0,1]
- 2. The reward for each action is i.i.d. (independent and identically distributed).
- 3. Reward distribution is the Bernoulli distribution.

$$R(t) = \mu^* \cdot t - \sum_{s=1}^t \mu(a_s)$$

Definition of Regret at round t.

R(t) is a random variable, so we should talk about expected regret E[R(T)].

Algorithm

- 1. Uniform exploration
- 2. Adaptive exploration
 - 2.1. Successive elimination algorithm
 - 2.2. UCB1 algorithm
 - 2.3. Thompson sampling

Uniform exploration

- 1 Exploration phase: try each arm N times;
- 2 Select the arm \hat{a} with the highest average reward (break ties arbitrarily);
- 3 Exploitation phase: play arm \hat{a} in all remaining rounds.

Algorithm 1.1: Explore-First with parameter N.

$$N = (T/K)^{2/3} \cdot O(\log T)^{1/3}$$
 Put this to N

Theorem 1.3. Explore-first achieves regret $\underline{\mathbb{E}[R(T)]} \leq T^{2/3} \times O(K \log T)^{1/3}$, where K is the number of arms.

Its performance in the exploration phase is terrible.

Uniform exploration & epsilon greedy

```
1 for each round t = 1, 2, ... do
2 | Toss a coin with success probability \epsilon_t;
3 | if success then
4 | explore: choose an arm uniformly at random
5 | else
6 | exploit: choose the arm with the highest average reward so far
7 end

Algorithm 1.2: Epsilon-Greedy with exploration probabilities (\epsilon_1, \epsilon_2, ...).
```

Theorem 1.4. Epsilon-greedy algorithm with exploration probabilities $\epsilon_t = t^{-1/3} \cdot (K \log t)^{1/3}$ achieves regret bound $\mathbb{E}[R(t)] \leq t^{2/3} \cdot O(K \log t)^{1/3}$ for each round t.

It is the same regret as in uniform exploration, but it holds for all rounds t. To get (epsilon t) ε_t from $\varepsilon_t \sim t^{-1/3}$

Uniform exploration With epsilon greedy

Both exploration-first and epsilon-greedy have a big flaw that the exploration schedule does not depend on the history of the observed rewards

Successive Elimination Algorithm

- 1 Alternate two arms until $UCB_t(a) < LCB_t(a')$ after some even round t;
- 2 Then abandon arm a, and use arm a' forever since.

Algorithm 1.3: "High-confidence elimination" algorithm for two arms

This approach extends to K > 2 arms as follows:

- 1 Initially all arms are set "active";
- 2 Each phase:
- 3 try all active arms (thus each phase may contain multiple rounds);
- 4 deactivate all arms a s.t. ∃arm a' with UCB_t(a) < LCB_t(a');
- 5 Repeat until end of rounds.

Algorithm 1.4: Successive Elimination algorithm

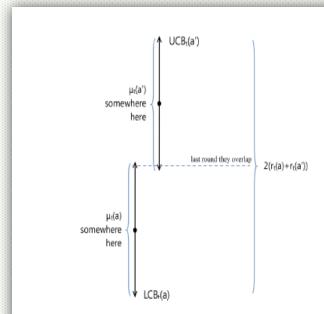

Figure 1.2: t is the last round that the two confidence intervals still overlap

Successive Elimination Algorithm

Lemma 1.6. For two arms, Algorithm 1.3 achieves regret $\mathbb{E}[R(t)] \leq O(\sqrt{t \log T})$ for each round $t \leq T$.

Theorem 1.8. Successive Elimination algorithm achieves regret

$$\mathbb{E}[R(t)] = O(\sqrt{Kt \log T})$$
 for all rounds $t \le T$.

Theorem 1.9. Successive Elimination algorithm achieves regret

$$\mathbb{E}[R(T)] \leq O(\log T) \left[\sum_{\text{arms a with } \mu(a) < \mu(a^*)} \frac{1}{\mu(a^*) - \mu(a)} \right].$$

The existence of logarithmic regret bounds is benefit of adaptive exploration compared to non-adaptive exploration.

UCB1 Algorithm

- 1 Try each arm once;
- 2 In each round t, pick $\underset{a \in \mathcal{A}}{\operatorname{argmax}} \operatorname{UCB}_t(a)$, where $\operatorname{UCB}_t(a) = \bar{\mu}_t(a) + r_t(a)$;

Algorithm 1.5: UCB1 Algorithm

$$r_t(a) = \sqrt{\frac{\alpha \cdot \ln t}{n_t(a)}}$$

Original version of confidence radius

Theorem 1.14. Algorithm UCB1 satisfies regret bounds in (1.9) and (1.11).

$$\mathbb{E}[R(t)] = O(\sqrt{Kt \log T}) \quad \text{for all rounds } t \le T. \tag{1.9}$$

$$\mathbb{E}[R(T)] \le O(\log T) \left[\sum_{\text{arms a with } \mu(a) < \mu(a^*)} \frac{1}{\mu(a^*) - \mu(a)} \right]. \tag{1.11}$$

A regret bound of the form C * f(T), where f(T) does not depend on the mean rewards μ , and the "constant" C does not depend on T.

Instance-independent

C does not depend on T

Instance-dependent Otherwise

$$\mathbb{E}[R(T)] \leq O(\log T) \left[\sum_{\text{arms a with } \mu(a) < \mu(a^*)} \frac{1}{\mu(a^*) - \mu(a)} \right]$$

Instance independent

Theorem 2.14. Fix K, the number of arms. Consider an algorithm such that

$$\mathbb{E}[R(t)] \le O(C_{\mathcal{I},\alpha} t^{\alpha})$$
 for each problem instance \mathcal{I} and each $\alpha > 0$. (2.15)

Here the "constant" $C_{\mathcal{I},\alpha}$ can depend on the problem instance \mathcal{I} and the α , but not on time t. Fix an arbitrary problem instance \mathcal{I} . For this problem instance:

There exists time
$$t_0$$
 such that for any $t \ge t_0$ $\mathbb{E}[R(t)] \ge C_{\mathcal{I}} \ln(t)$, (2.16)

for some constant $C_{\mathcal{I}}$ that depends on the problem instance, but not on time t.

Theorem 2.16. For each problem instance \mathcal{I} and any algorithm that satisfies (2.15), (a) the bound (2.16) holds with

$$C_{\mathcal{I}} = \sum_{a: \Delta(a) > 0} \frac{\mu^* (1 - \mu^*)}{\Delta(a)}.$$

(b) for each $\epsilon > 0$, the bound (2.16) holds with

$$C_{\mathcal{I}} = \sum_{a: \Delta(a) > 0} \frac{\Delta(a)}{\text{KL}(\mu(a), \mu^*)} - \epsilon.$$

Thompson Sampling

Theorem 3.12. Consider IID bandits with no priors. For Thompson Sampling with both approaches (i) and (ii) we have: $\mathbb{E}[R(T)] \leq \mathcal{O}(\sqrt{kT \log T})$.

Theorem 3.13. Consider IID bandits with no priors. For Thompson sampling with approach (i),

$$\mathbb{E}[R(T)] \le (1+\epsilon)(\log T) \underbrace{\sum_{\substack{arms \ a \\ \iota \Delta(a) > 0}} \frac{\Delta(a)}{KL(\mu(a), \mu^*)}}_{(*)} + \frac{f(\mu)}{\epsilon^2},$$

for all $\epsilon > 0$. Here $f(\mu)$ depends on the reward function μ , but not on the ϵ , and $\Delta(a) = \mu(a^*) - \mu(a)$.

Prior work considered two such "fake priors":

- (i) independent, uniform priors and 0-1 rewards,
- (ii) independent, Gaussian priors and Gaussian unit-variance rewards (so each reward is distributed as $\mathcal{N}(\mu(a), 1)$, where $\mu(a)$ is the mean).

Main definition. For each round t, consider the posterior distribution for the best arm a^* . Formally, it is distribution p_t over arms given by

$$p_t(a) = \mathbb{P}[a = a^* \mid H_t]$$
 for each arm a . (3.1)

Thompson Sampling is a very simple algorithm:

In each round
$$t$$
, arm a_t is drawn independently from distribution p_t . (3.2)

Sometimes we will write $p_t(a) = p_t(a|H_t)$ to emphasize the dependence on history H_t .

Alternative characterization. Thompson Sampling can be stated differently: in each round t,

- 1. sample reward function μ_t from the posterior distribution $\mathbb{P}_t(\mu) = \mathbb{P}(\mu|H_t)$.
- 2. choose the best arm \tilde{a}_t according to μ_t .

Let us prove that this characterization is in fact equivalent to the original algorithm.

Lemma 3.1. For each round t and each history H_t , arms a_t and \tilde{a}_t are identically distributed.

Proof. For each arm a we have:

$$\Pr(\tilde{a}_t = a) = \mathbb{P}_t(\operatorname{arm} a \text{ is the best arm})$$
 by definition of \tilde{a}_t

$$= \mathbb{P}(\operatorname{arm} a \text{ is the best arm}|H_t) \qquad \text{by definition of the posterior } \mathbb{P}_t$$

$$= p_t(a|H_t) \qquad \qquad \text{by definition of } p_t.$$

Thus, \tilde{a}_t is distributed according to distribution $p_t(a|H_t)$.
